## **Prompt**

What is the difference between machine learning and deep learning?

# Response

Machine learning and deep learning are both subfields of artificial intelligence (AI) that involve training algorithms to perform specific tasks. The key difference between them lies in the complexity and depth of the algorithms used.

## Machine Learning (ML):

Machine learning is a type of AI that enables computers to learn from data without being explicitly programmed. It involves training algorithms on labeled data to recognize patterns and make predictions or decisions. ML algorithms can be categorized into three types:

- 1. Supervised Learning: The algorithm learns from labeled data to predict outcomes.
- 2. Unsupervised Learning: The algorithm discovers patterns and relationships in unlabeled data.
- 3. Reinforcement Learning: The algorithm learns through trial and error by interacting with an environment.

Machine learning algorithms are typically shallow, meaning they have a limited number of layers (usually 1-2) and are designed to solve specific, well-defined problems. Examples of machine learning applications include:

- \* Image classification (e.g., recognizing objects in images)
- \* Natural Language Processing (NLP) for text classification or sentiment analysis
- \* Recommendation systems for personalized product suggestions

# Deep Learning (DL):

Deep learning is a subfield of machine learning that involves the use of neural networks with multiple layers

### First Most Valuable Data

(Skip) three types mainly differ from one other in the they use to train the machine.

- In Supervised Learning, the machine is trained using a certain dataset. (Skip)
- In Unsupervised Learning, the machine is not trained using an initial dataset but rather it has only a function which accepts certain arguments and after performing certain computations, an outcome is generated. (Skip)
- In Reinforcement Learning, the machine is yet again not trained on any initial dataset but then as the programme executes, it learns, formats its own mistakes and improves itself.(Skip)
- Like I mentioned before, Artificial Intelligence and Machine learning go hand in hand.(Skip)

### Second Most Valuable Data

(Skip) In supervised learning, the learning itself is what you care about. You've got your cost function, which you want to minimize. In unsupervised learning, the goal is always to help some other task, like classification or categorization. For example, I might ask a computer system to passively watch a lot of YouTube videos (so unsupervised learning happens here), then ask it to recognize objects with great accuracy (that's the final supervised learning task). (Skip)

- DB: What are some other areas where you see exciting progress?
- IS: A general direction that I believe to be extremely important is: are learning models capable of more sequential computations? I mentioned how I think that deep learning is successful because it can do more sequential computations than previous ("shallow") models. (Skip)

### Third Most Valuable Data

(Skip) Eleni: Can you clarify the difference between AI, machine learning, and deep learning?

Inga: Al is the umbrella over machine learning. Al, to me, is our hope for human intelligence exhibited by machines. There are multiple goals of Al, which are all facets of human intelligence. We can reason, accumulate knowledge, plan for things, manipulate objects, and communicate with each other with our language. Learning, of course, is a part of what makes us human.

Machine learning is the ability to learn without being explicitly programmed. The reason why machine learning has become so popular in recent years is that teaching a machine to learn—or building a machine that can learn on its own—can achieve all the goals of AI. It can learn how to reason, and understand our language, and perceive and move objects. You give a machine learning algorithm lots and lots of data and that algorithm learns the concepts around this data. It's then able to make a determination or prediction about something in the world.

Deep learning is the newest field of machine learning, and it has really catapulted us into the renaissance that we're in today. The "deep" in deep learning comes from multiple hidden layers of transformation in data. Examples of things that are enabled by deep learning are self-driving cars or the Google Translate app in which the camera on your phone can immediately translate text that it sees into a different language.(Skip)
